

# Assumptions

**Assumption 4:** A 'Vulnerability Scale' may be defined, based on the assessment of the system state in the (U, V)-space. Obviously, such a definition is not univocal. One possibility, hereby adopted, is:

Measure the **Vulnerability Index by the Euclidian distance of the state (U,V) to the cusp line** in the  $U \geq 0, V \geq 0$  region of the (U, V)-plane.

b) **Normalize the index such that, everywhere on the cusp line, including its  $V \rightarrow 0$  portion, the Vulnerability Index be equal to 100, that is - reach its assumed maximum.**

Thus, if D is the said the Euclidian distance to the cusp line, then the 'Vulnerability Index',  $V_{scale}$ , on the 0 – 100 - '*Vulnerability Scale*' - is:

$V_{scale} = 100(1-D/15)$ , where the (U, V) field has been conventionally limited to  $0 \leq U \leq 15, 0 \leq V \leq 15$ .

# Analytical Approach to QVA

$$\frac{-e^{\frac{u\zeta+v}{\theta}} + e^{-\frac{u\zeta+v}{\theta}}}{\left(\frac{1}{2}-\zeta\right)e^{\frac{u\zeta+v}{\theta}} - \left(\frac{1}{2}+\zeta\right)e^{-\frac{u\zeta+v}{\theta}}} + \frac{u}{\theta} = 2M$$

$$\frac{\frac{1}{2}\left(e^{\frac{u\zeta+v}{\theta}} - e^{-\frac{u\zeta+v}{\theta}}\right) - \zeta\left(e^{\frac{u\zeta+v}{\theta}} + e^{-\frac{u\zeta+v}{\theta}}\right)}{e^{\frac{u\zeta+v}{\theta}} - e^{-\frac{u\zeta+v}{\theta}}} = \frac{1}{\frac{u}{\theta} - 2M}$$

$$\frac{1}{2} - \zeta \coth\left(\frac{u\zeta+v}{\theta}\right) = \frac{1}{\frac{u}{\theta} - 2M}$$

$$\coth\left(\frac{u\zeta+v}{\theta}\right) = \left(\frac{1}{2} - \frac{1}{\frac{u}{\theta} - 2M}\right) \frac{1}{\zeta} \approx \frac{1}{2\zeta}$$

$$\tanh\left(\frac{u\zeta+v}{\theta}\right) = 2\zeta$$

*Equation of State*

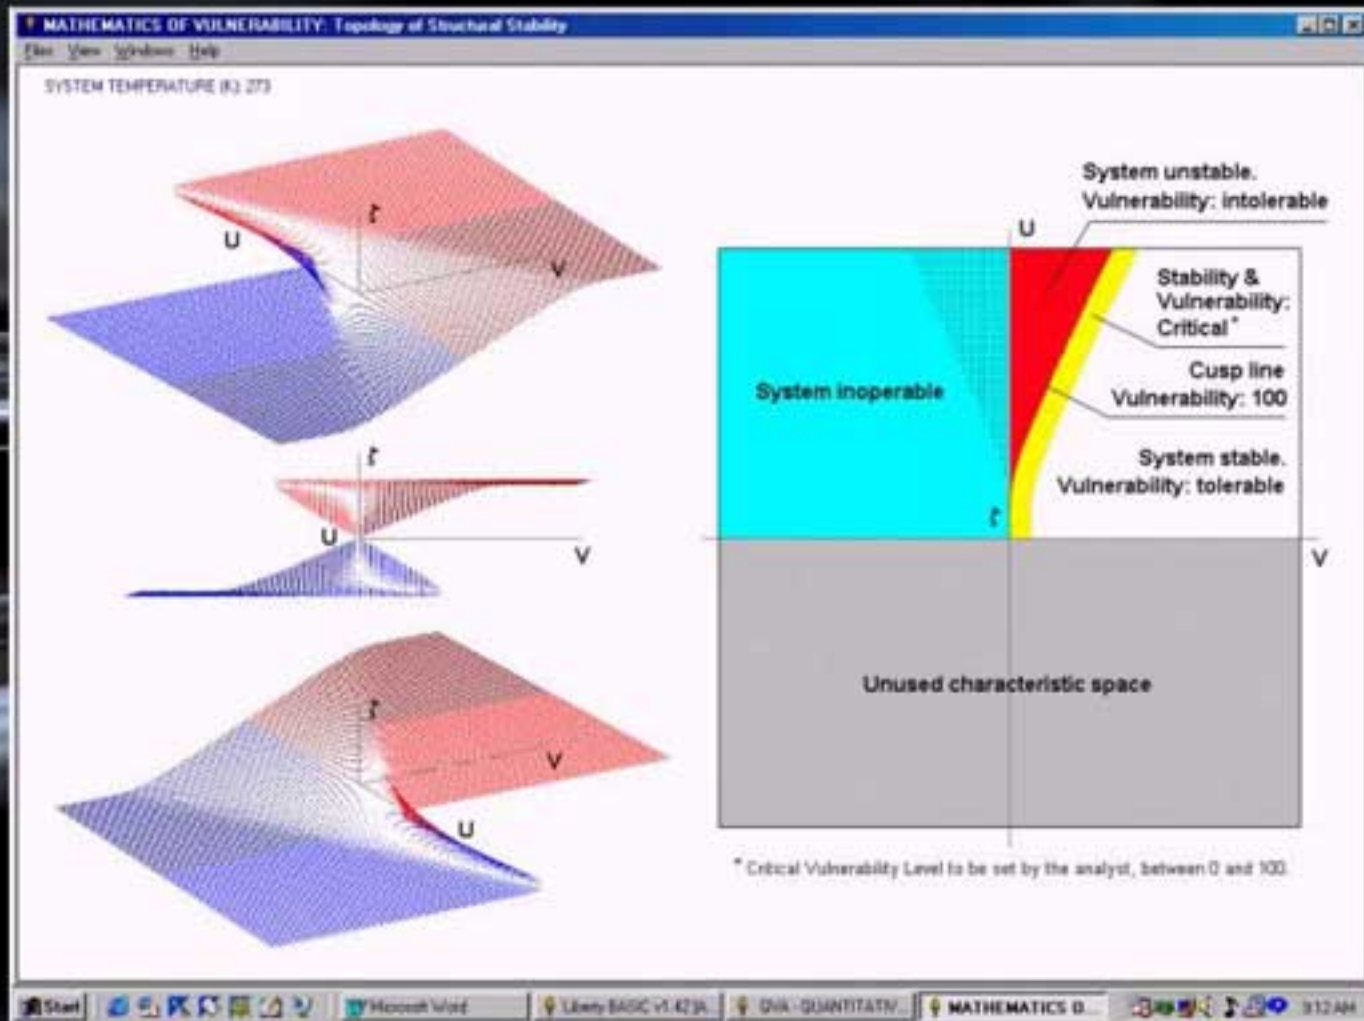

# The Vulnerability Equation of State

$$\tanh\left(\frac{u\zeta + v}{\theta}\right) = 2\zeta$$

- Where
- $u$  : Internal-type Indicators
  - $v$  : External-type Indicators
  - $\theta$  : Degree of Induced Stress into The System
  - $\zeta$  : Vulnerable State Space Indicator

**VULNERABILITY ANALYSIS**

System's monitored parameter the control variables U as for vulnerability analysis

Let it be reminded that U varying process parameters whereas V is obtained by a that are rather exterior to of the capability of manag

In consideration of their membership functions of the indicators (see e.g. the B acceptability).

Accordingly, if  $X_i, i = 1, \dots, n$  indicators contributing in  $U(X_1, X_2, \dots, X_n) = \min_i$  where  $X_i$  are obtained from  $X_i = A \lg(Y_i) + B, i = 1, \dots, n$

The constants A and B are, knowledge of two pair of v indicators:

$$A \lg(Y_{i1}) + B = 0.2$$

$$B \lg(Y_{i2}) + B = 0.6$$

wherefrom

$$A = 0.4 / (\lg(Y_{i2}) - \lg(Y_{i1}))$$

$$B = (0.6 \lg(Y_{i1}) - 0.2 \lg(Y_{i2})) / (\lg(Y_{i2}) - \lg(Y_{i1}))$$

# VULPET VARIABLES AND RELATED ISSUES

---

## The Vulnerability Index

The *Vulnerability Index* is a measure of the distance of the point-state of the system in its (U,V) space, to the cusp line - the limit for the 'Intolerable Vulnerability', or 'red', basin. While more analytical details may be obtained from Section 10.5, that also explains the notion of '*Residual Vulnerability*', the following are noteworthy at this time:

The meaning of the grades for Vulnerability Index is as follows:

Grade	Definition
Low	Vulnerability Index is low, and thereby system stability is considered high.
Medium	Vulnerability Index takes a median position in the 0-100 range, and thereby system stability is considered tolerable.
High	Vulnerability Index is high, and thereby system stability is considered low.

The grades are based on comparisons against peers within a defined industry segment. Guidelines specific to those industry segments are being used in the assessments.

## The Vulnerability Matrix

The Vulnerability Matrix field of values is spanned by two aggregated indices, generated from plant indicators and relating to the Vulnerability Index (see 10.1) - and thereby to the U and V variables. These are:

- (i) the *System Deficiency Index* (U), and
- (ii) the *Management Deficiency Index* (1-V).

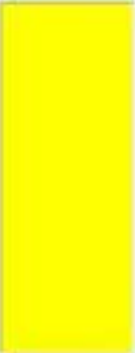

A pair of such indices features, at any time, the *vulnerability state (condition) of the plant* and corresponds to a 'point-state' in the field of the matrix.

The analytical manner of building *indexes* U and V from hosts of *indicators* of [u], and [v] types, respectively is derived from the Fuzzy Set theory of impact indicators, and is explained at some length in the chief reference paper, readable at code's runtime from the *Vulnerability Assessment Machine*' module - the 'Help' menu.

The appraisal of the vulnerability grades that result from such an analysis is based on comparisons against industry standards within a defined industry segment. Guidelines specific to those industry segments are being used in the assessments.

Grade	Definition
	<ul style="list-style-type: none"> <li>• Expectation exceeded.</li> <li>• Minor or insignificant deficiency (-ies) may exist.</li> <li>• Strive for perfection or proactive behavior exceeds compliance.</li> <li>• Best in class, or exemplifying some of the best practices in the industry.</li> </ul> <p><b>Equivalent words: Good, Above standard.</b></p> <ul style="list-style-type: none"> <li>• Most expectations met.</li> <li>• Noteworthy deficiencies (-y) exist(s).</li> <li>• Compliance secured.</li> <li>• Acceptable standards evidenced, yet with room for improvement.</li> </ul> <p><b>Equivalent words: Adequate, Standard.</b></p>
	<ul style="list-style-type: none"> <li>• Expectations partially met.</li> <li>• Significant deficiencies (-y) exist(s).</li> <li>• Reactive behavior, leaning towards doing the minimum</li> <li>• Some areas are below the standard of current day practice, with considerable potential for improvement.</li> </ul> <p><b>Equivalent words: Fair, Below Standard, Improvement needed.</b></p>
	<ul style="list-style-type: none"> <li>• Expectations not met.</li> <li>• Critical deficiencies (-y) exist(s).</li> <li>• Defensive behavior, culture of 'cutting corners'.</li> <li>• Embodies few or none of the standards expected, of current day practice, with major</li> </ul>

## VULNERABILITY

Offset: 6      Tolerability: 75%

**VULNERABILITY INDEX and RESIDUAL VULNERABILITY.**

Defining the Vulnerability Index,  $V_{index}$ , as

$$V_{index} = 100(1-d/15),$$

with  $d$  the distance of the system's point-state to the cusp and 15 - a graphics scale factor, has as a result, inter alia, the fact that even when the system is at its best (all indicators at zero), the relative position of the point-state to the cusp is such that  $V_{index}$  may not reach its zero-value - this depending on 'temperature'.

At 273 K, the Residual Vulnerability is 0.26.

Temperature @Q: 273

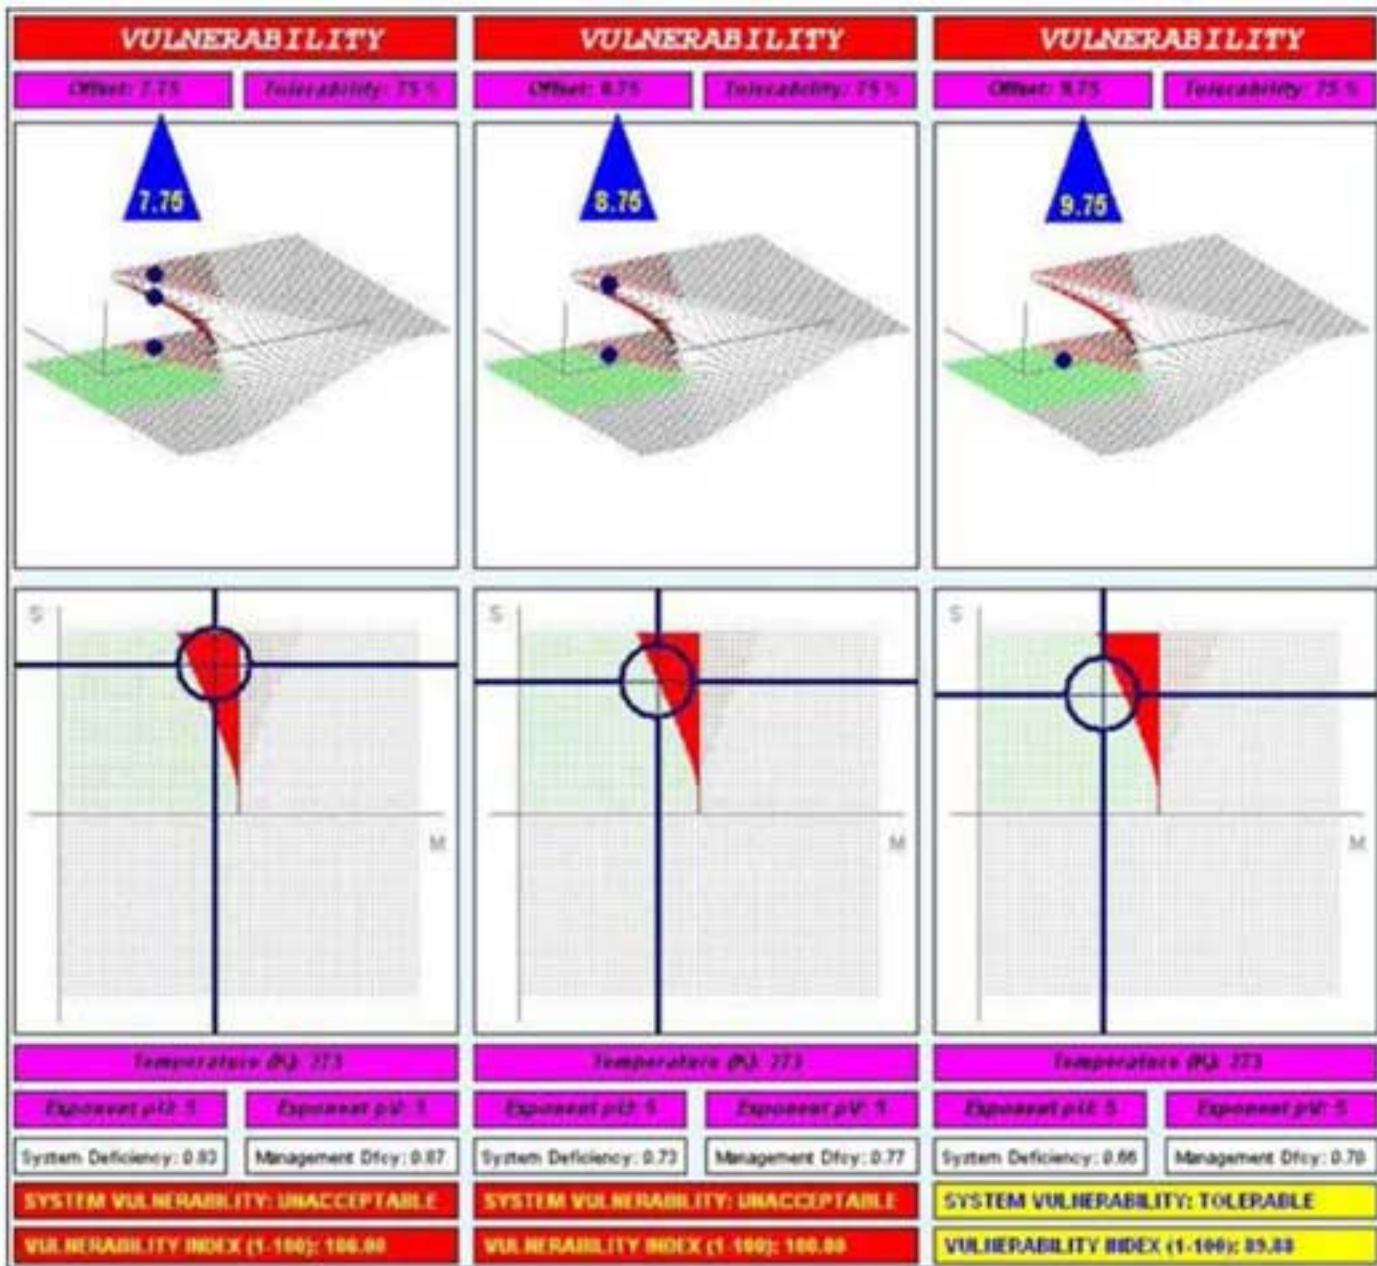

$L = 0$ 
 $v = 1$

SYSTEM VULNERABILITY: ACCEPTABLE

VULNERABILITY INDEX AT 273: 0.26

Effect of different Indicator Range Offsets: 7.75 (default), 8.75, and 9.75.

Observe relative position of extreme point state (the state system *cannot go beyond*, even if all scores are at their worst, i.e. 3) and instability area.

## The 'Residual Vulnerability' .

The figures that follow provide a straightforward and indeed 'graphical' explanation on why, when ALL indicators are at their best, that is - at the 0 (zero) level prescribed by the Swiss Re wisdom on the matter of plant condition, the Vulnerability Index may happen to *not* be reaching its zero value. Please read carefully the insets.

As a general remark, the lower the 'temperature', the higher the vulnerability - even the residual one - which is consistent with the physical analogy on which the model rests, implying that at lower temperatures *the cooperative effects* (that play a leading part in the onset of system's instability) are stronger.

## The 'Tolerability' - a Stakeholder's Privilege.

In a similar manner, the figures in the sequel explain 'Tolerability' - a variable which, while not exactly a 'model control parameter', controls however *the relationship between model and user*, in the sense that it allows the user to determine *the borderlines between the 'acceptable' - or 'green', the 'tolerable' - or 'yellow' and the 'unacceptable' - or 'red', basins in system's space (U, V), in terms of Vulnerability Index*. Please read the insets.

## The VULPET Implementation of the QVA Model.

The generic concept of the quantitative vulnerability assessment (QVA) employed with VULPET is described in section 4.1. The adaptation of the generic QVA model to the analysis of vulnerabilities in petrochemical plants, and in a manner relevant to the reinsurance business, has required – in the QVA terminology:

- a) The definition of appropriate variables underlying the  $(U, V, \zeta)$  space of most probable states of the system (the cuspidal foil), and the Vulnerability Matrix, respectively. VULPET has adopted:
  - A *System Deficiency Index*, named  $S$ , relating to model variable  $U$ , and spanning the  $y$ -cartesian axis;
  - A *Management Deficiency Index*, named  $M$ , relating to model variable  $V$ , and spanning the  $x$ -cartesian axis.
  
- b) A proper choice of the origin ( $S = 0, M = 0$ ) in the model's  $(U, V)$  plane, guided by the principle that, *whenever either  $S$  or  $M$  are incremented, the system vulnerability should increase* – a principle of common sense, consistent with the notion that  $S$  and  $M$  are *deficiency*-relating indexes (the higher a deficiency, the higher the vulnerability). The choice  $S = U, M = V + 1$  was found to satisfy the terms above, which places the said origin,  $S=0, M=0$ , at model's  $U=0, V= -1$ , respectively. Consistently, the two extreme cases of vulnerability allowed by the VULPET implementation of the QVA method are as rendered in *Figure 4.2.1*.
  
- c) The definition of appropriate sets of indicators featuring the internal (system) variables contributing in the construction of the  $S$  variable (the '[u]-type indicators'), and the external (influence) variables contributing in the construction of the  $M$  variable (the '[v]-type indicators'). VULPET comes with two sets of indicators, each in two versions:
  - A '*short*' set, of 26 indicators, without and with indicator interdependence, respectively, and
  - A '*long*' set, of 105 indicators, without and with indicator interdependence, respectively.

The VULPET code takes the *long set with interdependence* as the default.

# Calibrating Models for Vulnerability Assessment

The interplay of the model control parameters explained in section 4.2 favors one essential operation in making VULPET a meaningful tool of petrochemical plants vulnerability assessment: the *calibration*.

*Calibrating means to set (i) the Temperature; (ii) the Indicator Range Offset; and (iii) the U/V-Constructor Function Exponents  $pU$  and  $pV$  so that, for known vulnerability conditions of reference plants and the respective indicator scores, the point-state of the system fall in an appropriate place in the Vulnerability Matrix Field spanned by the System Deficiency Index,  $S$ , and the Management Deficiency Index,  $M$ .*

The assumption underlying the model calibration is – as usual in the modeling and measuring trade – that,

*Once a sufficient number of cases are well represented, in average, by an established set of model control parameters like the temperature, the offset, and  $pU$  and  $pV$ , one may assume with an acceptable degree of confidence that the model is able to determine with a sufficient accuracy the Vulnerability Index, and condition (acceptable, tolerable, unacceptable), of any enterprise that came under assessors' scrutiny and has been properly scored.*

Numerical experiments conducted with VULPET on a series of cases on record with Swiss Re has resulted in the following *terms of calibration*:

Background	The principalities of Wallachia and Moldavia - for centuries under the suzerainty of the Turkish Ottoman Empire - secured their autonomy in 1856; they united in 1859 and a few years later adopted the new name of Romania. The country gained recognition of its independence in 1878. It joined the Allied Powers in World War I and acquired new territories - most notably Transylvania - following the conflict. In 1940, Romania allied with the Axis powers and participated in the 1941 German invasion of the USSR. Three years later, overrun by the Soviets, Romania signed an armistice. The post-war Soviet occupation led to the formation of a Communist "people's republic" in 1947 and the abdication of the king. The decades-long rule of dictator Nicolae CEAUSESCU, who took power in 1965, and his Securitate police state became increasingly oppressive and draconian through the 1980s. CEAUSESCU was overthrown and executed in late 1989. Former Communists dominated the government until 1996 when they were swept from power. Romania joined NATO in 2004 and the EU in 2007.
